

# AI Certification and Assessment Catalogues: Practical Use and Challenges in the Context of the European AI Act

GREGOR AUTISCHER, Graz University of Technology, Austria

KERSTIN WAXNEGGER, Know Center Research GmbH, Austria

DOMINIK KOWALD, Know Center Research GmbH & Graz University of Technology, Austria

Certifying artificial intelligence (AI) systems remains a complex task, particularly as AI development has moved beyond traditional software paradigms. We investigate the certification of AI systems, focusing on the practical application and limitations of existing certification catalogues, by attempting to certify a publicly available AI system. We aim to evaluate how well current approaches work to effectively certify an AI system, and how AI systems, that might not be actively maintained or initially intended for certification, can be selected and used for a sample certification process. Our methodology involves leveraging the Fraunhofer AI Assessment Catalogue as a comprehensive tool to systematically assess an AI model's compliance with certification standards, focusing on reliability and fairness. We find that while the catalogue effectively structures the evaluation process, it can also be cumbersome and time-consuming to use. We observe the limitations of an AI system that has no active development team any more and highlight the importance of complete system documentation. Finally, we identify some limitations of the used certification catalogues and propose ideas on how to streamline the certification process.

Keywords: Algorithmic Auditing, Artificial Intelligence, Certification Catalogues, Algorithmic Fairness, AI Reliability

In *Proceedings of Fourth European Workshop on Algorithmic Fairness (EWAF'25)*. Proceedings of Machine Learning Research, 6 pages.

## 1 Introduction and Motivation

Artificial intelligence (AI) has evolved, over several decades, to complex machine learning (ML) systems. Recently, AI systems were increasingly integrated into our daily lives, moving from specialized research labs to mainstream applications [7]. Today, AI is utilized in many domains such as healthcare [27], human resources [37], industry [10], research [13], finance [6], and in prominent technologies such as recommender systems for e.g., social networks [17, 19, 20]. AI now plays a significant role in shaping our interactions with technology and informing decision-making processes across various sectors [16]. The rapid proliferation of AI applications has raised concerns about safety, privacy, fairness, and further ethical implications [3, 18]. In response to these challenges, AI governance has become an increasingly prominent focus for legislators and policymakers worldwide [33]. The European Union's

AI Act, for instance, represents a landmark piece of legislation that aims to establish a comprehensive regulatory framework for AI systems [21]. Since its introduction, certification of AI systems to prove compliance is now more important than ever. AI certification must address a broad spectrum of concerns, including prediction accuracy, fairness, transparency, and should consider aspects related to ethics and reproducibility [30, 31, 39].

In our work, we aim to bridge the gap between theoretical certification frameworks and their practical application. We attempt to certify an existing open-source AI system (emotion recognition in an art installation [23, 24]) using current certification frameworks. We primarily use the Fraunhofer AI Assessment Catalogue [26] and we draw comparisons to other catalogues. With this approach, we aim to:

- Identify which parts of the catalogue are most useful and if simplifications or refinements could be beneficial.
- Provide a more practical understanding of the AI certification process, focusing on fairness and reliability.
- Discover the limitations where sample certifications encounter challenges.

## 2 Background

The growing deployment of AI in critical areas underscores the need for stricter regulation, as seen in approved medical systems that set a precedent for future frameworks [25, 28]. Worldwide, several organizations are advancing policy initiatives [22]. The most comprehensive and important for our work is the EU AI Act.

### 2.1 EU Artificial Intelligence Act

The European Union’s AI Act is currently the most significant and far-reaching regulatory initiative in the field of AI, and it took effect on 1st of August 2024. The impact of the AI Act will extend far beyond the EU’s borders, potentially setting global standards for AI management [11]. The AI Act has broad coverage for AI systems used within the European Union. The AI Act defines AI systems broadly and technology-neutrally, emphasizing functional characteristics rather than specific technologies (i.e., spanning from basic statistics-based to complex neural network-based predictions) [11]. This approach moves away from earlier, restrictive definitions, ensuring the framework remains applicable to current and future AI developments [12]. The AI Act categorizes AI systems into various risk levels and imposes corresponding requirements, with stricter regulations for higher-risk applications [11]. Key risk categories include: prohibited AI systems, high-risk AI systems, general-purpose AI systems, AI systems with special transparency obligations, and limited-risk AI systems.

### 2.2 Other Initiatives

Internationally, countries like the US have discussed a Blueprint for an AI Bill of Rights [38]. Japan has discussed developing AI guidelines emphasizing a multi-layered governance framework [9], and has recently even introduced a bill on AI risk management [32]. The recent AI Action Summit in Paris, also reflects the global acknowledgment of the need for AI regulation [34].

### 2.3 Certifying AI

Certification plays a critical role in proving compliance and fostering user trust [5], but AI certification differs significantly from traditional software certification due to AI’s inherent opacity [39]. CEN, CENELEC, and ETSI bridge the gap between EU regulations and practical certification frameworks [14]. Furthermore, organizations like

ISO, IEC, and IEEE are also working on standards, they have yet to establish a comprehensive process connecting certification and applicable law [22]. The rapidly evolving nature of AI technology poses major challenges for creating and maintaining effective standards [8]. This underscores the urgent need for a broad framework that addresses AI’s adaptability and complexity [4]. Addressing these dynamic aspects is essential to develop robust certification practices that are compliant with the EU AI Act.

## 2.4 AI Certification Catalogues

Several organizations have created AI certification guidelines, including the “Guideline for Designing Trustworthy Artificial Intelligence” by Fraunhofer [26], the “Trusted Artificial Intelligence” initiative by TÜV [39], or the “Auditing Machine Learning Algorithms” proposal by supreme audit institutions in the EU [29]. In this work, we focus on applying the Fraunhofer certification catalogue as described in the following.

## 3 Methodology for Certification

We applied the Fraunhofer AI Certification Catalogue to an existing AI system to explore and evaluate the certification process. Our first important step was to find and define an AI system. We chose the facial emotion recognition component of the RIOT art installation [35], which uses the EmoPy framework [1] for facial emotion recognition. It uses this technology to interactively adapt the plot of a film [15]. We selected this system because it is open-source, appears well-documented, and is integrated into a larger application context. Additionally, emotion recognition is a high risk AI application according to the EU AI Act. First, we compiled a list of all available documentation, like the RIOT GitHub repository [36] or articles describing the ML component [23, 24], and filled in some information gaps beforehand to have a complete set of information for our certification attempt.

We used the Fraunhofer Catalogue as the primary certification framework due to its comprehensive nature and full public availability. In practice, our certification began by defining the AI system and its boundaries, then outlining its life cycle. We specifically focused on the two risk dimensions of fairness and reliability, which are the most important dimensions we identify in the protection requirement analysis. The Fraunhofer Catalogue functions like a structured questionnaire, guiding us through each certification step, leading to our certification decision [26]. After completing this certification process, we analysed and addressed its key aspects and drew conclusions about the challenges we encountered. We also examined how the two alternative catalogues we mentioned differ from, and potentially complement, the Fraunhofer approach. Finally, we discussed the limitations and applicability of these findings, acknowledging both the constraints of our chosen AI application, namely emotion recognition in an art installation, and the broader challenges of certifying AI systems.

## 4 Key Findings and Limitations

We performed a sample certification of a facial emotion recognition system using the Fraunhofer Catalogue. In the following, we discuss key aspects and questions of our sample AI certification:

*Which parts of the catalogue are most useful, and could there be simplifications or refinements?* The AI lifecycle overview proved especially helpful for gaining a comprehensive understanding of the system’s functionality, while the detailed risk assessment ensured thorough coverage of potential issues. However, the high level of detail occasionally led to nearly redundant questions, suggesting that a different structuring could streamline the process.

Additionally, the catalogue’s exclusive focus on documentation, rather than direct examination of code, can be a strength when dealing with proprietary systems, but it may benefit from supplementary technical checkpoints, such as those in the TÜV [39] or the “Auditing Machine Learning Algorithms” catalogues [29].

*Providing a more practical understanding of the AI certification process.* Selecting a system with solid documentation and a clear real-world context was crucial for a meaningful certification attempt. The Fraunhofer Catalogue’s step-by-step, questionnaire-like structure was generally effective in guiding us from initial system definition through risk analysis to a cross-dimensional assessment, although the process was time-intensive due to its thoroughness. To focus, our study we did not fully assess all risk dimensions. Even among the ones we did examine (fairness and reliability), we encountered shortcomings. Most notably, the system’s fairness dimension failed to meet the certification criteria due to significant gaps in identifying potential biases and discrimination risks, coupled with the absence of clearly defined metrics (see also the full Arxiv version of this article [2]).

*Discovering the limitations where sample certifications encounter challenges.* Key limitations were that the system was no longer actively developed and that it was never initially built for certification. Therefore, the system had insufficient documentation in places, notably in the fairness dimension. In our case, these information gaps were not resolved by developers, as the system was no longer in active development. In a typical real-world scenario, certification findings would lead to refinements, underscoring the importance of ongoing development support. The lack of an iterative feedback loop meant that shortcomings could not be resolved within this project, highlighting how real-world AI certifications must allow for continuous improvements and collaboration.

Summed up, the Fraunhofer Catalogue, with its strong emphasis on documentation, effectively pinpoints critical risks, but requires considerable time, comprehensive system documentation, and an active feedback process with developers to achieve a successful certification. Our findings illustrate the practical challenges and underscore the need for refinements and ongoing collaboration to ensure robust, real-world AI certification.

## 5 Conclusion and Future Research Directions

We highlight the complexity and shortcomings found in a sample AI certification, focusing on fairness and reliability. The implementation of the Fraunhofer AI Assessment Catalogue demonstrated its effectiveness as a comprehensive certification tool, particularly in its systematic approach to evaluate AI systems. We also found that the approach is, at times, bulky and time-consuming. The certification process revealed the necessity for thorough documentation and an active developer team, as their absence significantly undermines feasibility. Our findings address the initial research objectives by showing both effective aspects and shortcomings of the current approach. In future works, other certification catalogues and methodologies should be considered or integrated to potentially streamline the process. Another research path is to continue the certification attempt by incorporating feedback directly into the AI system design, ultimately resulting in a fully certifiable AI application and allowing for more in-depth analysis of a complete certification cycle. Further research could also focus on developing more flexible certification methods that adapt to various system states and development scenarios.

## Acknowledgments
